

Homework13

Problem 1 Paramagnetic susceptibility of liquid oxygen

How large is the magnetic moment of 1 g of liquid oxygen in a field of 1.8 tesla, according to the data in Table in Lec 21-1? Given that the density of liquid oxygen is 850 kg/m^3 at 90 K, what is its paramagnetic susceptibility χ_m ?

Problem 2 Earth dipole

At the north magnetic pole the earth's magnetic field is vertical and has a strength of 0.62×10^{-5} tesla. The earth's field at the surface and further out is approximately that of a central dipole.

(a) What is the magnitude of the dipole moment in joules/tesla?

(b) Imagine that the source of the field is a current ring on the "equator" of the earth's metallic core, which has a radius of 3000 km, about half the earth's radius. How large would the current have to be?

Problem 3 Rotating a bacterium

In magnetite, Fe_3O_4 , the saturation magnetization M_0 is $4.8 \cdot 10^5$ joule/(tesla \cdot m³). The magnetic bacteria discovered in 1975 by R. P. Blakemore contain crystals of magnetite, approximately cubical, of dimension $5 \cdot 10^{-8}$ m. A bacterium, itself about 10^{-6} m in size, may contain from 10 to 20 such crystals strung out as a chain. This magnet keeps the whole cell aligned with the earth's magnetic field, and thus controls the direction in which the bacterium swims; see Blakemore and Frankel (1981). Calculate the energy involved in rotating a cell containing such a magnet through 90° in the earth's field (assuming initial alignment), and compare it with the energy of thermal agitation, $k_B T$.
